Amirkabir Urtweelly of Technology

- ▶ Engineers desired to model the systems by mathematical models.
- ightharpoonup This model can be expressed by operator f from input space u into an output space y.
- **System Identification problem:** is finding  $\hat{f}$  which approximates f in desired sense.
  - ► Identification of static systems: A typical example is pattern recognition:
    - ▶ Compact sets  $u_i \in \mathcal{R}^n$  are mapped into elements  $y_i \in \mathcal{R}^m$  in the output
  - ▶ Identification of dynamic systems: The operator f is implicitly defined by I/O pairs of time function  $u(t), y(t), t \in [0, T]$  or in discrete time:

$$y(k+1) = f(y(k), y(k-1), ..., y(k-n), u(k), ..., u(k-m)),$$
(1)

lackbox In both cases the objective to determine  $\hat{f}$  is

$$\|\hat{y} - y\| = \|\hat{f} - f\| \le \epsilon$$
, for some desired $\epsilon > 0$ .

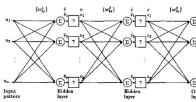

- ▶ Behavior of systems in practice are mostly described by dynamical models.
- ▶ ∴ Identification of dynamical systems is desired in this lecture.
- ▶ In identification problem, it is always assumed that the system is stable

Farzaneh Abdollahi Neural Networks Lecture 7 <u>3/30</u>

# Amirkabin

### Representation of Dynamical Systems by Neural Networks

- 1. Using Static Networks: Providing the dynamics out of the network and apply static networks such as multilayer networks (MLN).
  - Consists of an input layer, output layer and at least one hidden layer
  - ▶ In fig. there are two hidden layers with three weight matrices  $W_1$ ,  $W_2$  and  $W_3$ and a diagonal nonlinear operator  $\Gamma$  with activation function elements.
  - Each layer of the network can be represented by  $N_i[u] = \Gamma[W_i u]$ .
  - ► The I/O mapping of MLN can be represented by y = N[u] = $\Gamma[W_3\Gamma[W_2\Gamma[W_1u]]] = N_3N_2N_1[u]$
  - $\blacktriangleright$  The weights  $W_i$  are adjusted s.t min a function of the error between the network output y and desired output  $y_d$ .

A three layer neural network.

Farzaneh Abdollahi Neural Networks Lecture 7 4/30

- ▶ The universal approximation theorem shows that a three layers NN with a backpropagation training algorithm has the potential of behaving as a universal approximator
- ▶ Universal Approximation Theorem: Given any  $\epsilon > 0$  and any  $\mathcal{L}_2$ function  $f:[0,1]^n \in \mathbb{R}^n \to \mathbb{R}^m$ , there exists a three-layer backpropagation network that can approximate f within  $\epsilon$  mean-square error accuracy.

Farzaneh Abdollahi Neural Networks Lecture 7 5/30

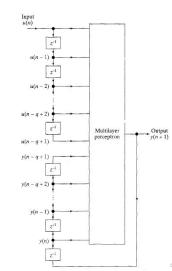

- Providing dynamical terms to inject to static networks:
  - 1. Tapped-Delay-Lines (TDL): Consider (1) for identification (I/O Model)

$$y(k+1) = f(y(k), y(k-1), ..., y(k-n), u(k), ..., u(k-m)),$$

- ▶ Dynamical terms u(k-j), y(k-i) for i = 1, ..., n, i = 1, ..., m is made by delay elements out of the network and injected to the network as input.
- ► The static network is employed to approximate the function f
- ► ∴ The model provided by the network will be

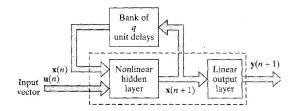

$$\hat{y}(k+1) = \hat{f}(\hat{y}(k), \hat{y}(k-1), ..., \hat{y}(k-n), u(k), ..., u(k-m)),$$

Farzaneh Abdollahi Neural Networks Lecture 7 6/30

Considering State Space model:

$$x(k+1) = f(x(k), x(k-1), ..., x(k-n), u(k), ..., u(k-m)),$$
  
 $y(k) = Cx(k)$ 

Farzaneh Abdollahi Neural Networks Lecture 7

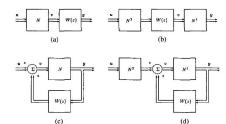

#### 2 Filtering

- in continuous-time networks the delay operator can be shown by integrator.
- The dynamical model can be represented by an MLN,  $N_1[.]$ , + a transfer matrix of linear function, W(s).
- ► For example:

$$\dot{x}(t) = f(x, u) \pm Ax,$$

- where A is Hurwitz. Define g(x, u) = f(x, u) - Ax
- $\dot{x} = g(x, u) + Ax$
- Fig, shows 4 configurations using filter.

Farzaneh Abdollahi Neural Networks Lecture 7 8/30

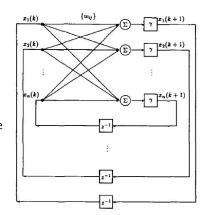

Amirkabin

- Using Dynamic Networks: Time-Delay Neural Networks (TDNN) [1], Recurrent networks such as Hopfield:
  - $\triangleright$  Consists of a single layer network  $N_1$ , included in feedback configuration and a time delay
  - Can represent discrete-time dynamical system as:

$$x(k+1) = N_1[x(k)], x(0) = x_0$$

- ▶ If  $N_1$  is suitably chosen, the solution of the NN converge to the same equilibrium point of the system.
- ▶ In continuous-time, the feedback path has a diagonal transfer matrix with  $1/(s-\alpha)$ in diagonal.
- ▶ : the system is represented by  $\dot{x} = \alpha x + N_1[x] + I$

The Hopfield network.

Farzaneh Abdollahi Neural Networks Lecture 7 9/30

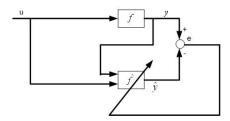

#### Neural Networks Identification Model

- ► Two principles of identification problems:
  - 1. Identification model
  - 2. Method of adjusting its parameters based on identification error e(t)
- ▶ Identification Model
  - 1. Direct modeling:
    - it is applicable for control, monitoring, simulation, signal processing
    - ▶ The objective: output of NN  $\hat{y}$  converge to output of the system y(k)
    - ▶ ∴ the signal of target is output of the system
    - ▶ Identification error  $e = y(k) \hat{y}(k)$  can be used for training.
    - ► The NN can be a MLN training with BP, such that minimizes the identification error.
    - ▶ The structure of identification shown in Fig named Parallel Model

Forward model

#### **Direct Modeling**

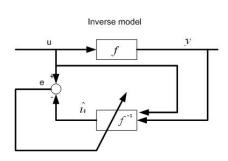

- Drawback of parallel model: There is a feedback in this model which some times makes convergence difficult or even impossible.
  - 2. Series-Parallel Model
    - ▶ In this model the output of system is fed to the NN

Farzaneh Abdollahi Neural Networks Lecture 7 11/30

# **Inverse Modeling**

- ▶ It is employed for the control techniques which require inverse dynamic
- ▶ Objective is finding  $f^{-1}$ , i.e.,  $V \rightarrow U$
- ▶ Input of the plant is target, u
- Error identification is defined.  $e = \mu - \hat{\mu}$

Farzaneh Abdollahi Neural Networks Lecture 7 12/30

#### Amirkabir University of Technology

### Example 1: Using Filtering

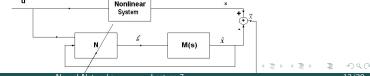

Consider the nonlinear system

$$\dot{x} = f(x, u) \tag{2}$$

- ▶  $u \in R^m$ : input vector,  $x \in R^n$ : state vector, f(.): an **unknown** function.
- Open loop system is stable.
- Objective: Identifying f
- ► Define filter:
  - Adding Ax to and subtracting from (2), where A is an **arbitrary** Hurwitz matrix  $\dot{x} = Ax + g(x, u)$  (3)

where 
$$g(x, u) = f(x, u) - Ax$$
.

▶ Corresponding to the Hurwitz matrix A,  $M(s) := (sI - A)^{-1}$  is an  $n \times n$  matrix whose elements are stable transfer functions.

Farzaneh Abdollahi Neural Networks Lecture 7 13/30

$$\dot{\hat{x}} = A\hat{x} + \hat{g}(\hat{x}, u)$$

- ▶ The identification scheme is based on the *parallel* configuration
  - ▶ The states of the model are fed to the input of the neural network.
  - ▶ an MLP with at least three layers can represent the nonlinear function g as:

$$g(x, u) = W\sigma(V\bar{x})$$

- W and V are the ideal but unknown weight matrices
- $\bar{x} = [x \ u]^T$
- $\bullet$   $\sigma(.)$  is the transfer function of the hidden neurons that is usually considered as a sigmoidal function:

$$\sigma_i(V_i\bar{x}) = \frac{2}{1 + exp^{-2V_i\bar{x}}} - 1$$

- $\blacktriangleright$  where  $V_i$  is the *ith* row of V,
- $\sigma_i(V_i\bar{x})$  is the *ith* element of  $\sigma(V\bar{x})$ .

15/30

g can be approximated by NN as

$$\hat{g}(\hat{x}, u) = \hat{W}\sigma(\hat{V}\hat{x})$$

► The identifier is then given by

$$\dot{\hat{x}}(t) = A\hat{x} + \hat{W}\sigma(\hat{V}\hat{x}) + \epsilon(x)$$

- $\bullet$   $\epsilon(x) \leq \epsilon_N$  is the neural network's bounded approximation error
- the error dynamics:

$$\dot{\tilde{x}}(t) = A\tilde{x} + \tilde{W}\sigma(\hat{V}\hat{x}) + w(t)$$

- $\tilde{x} = x \hat{x}$ : identification error
- $\tilde{W} = W \hat{W}, w(t) = W[\sigma(V\bar{x}) \sigma(\hat{V}\hat{x})] \epsilon(x)$  is a bounded disturbance term, i.e,  $||w(t)|| \leq \bar{w}$  for some pos. const.  $\bar{w}$ , due to the sigmoidal function.

Objective function  $J = \frac{1}{2}(\tilde{x}^T \tilde{x})$ 

Lecture 7

#### ► Training:

Updating weights:

$$\dot{\hat{W}} = -\eta_1 \left(\frac{\partial J}{\partial \hat{W}}\right) - \rho_1 \|\tilde{x}\| \hat{W}$$

$$\dot{\hat{V}} = -\eta_2 \left(\frac{\partial J}{\partial \hat{V}}\right) - \rho_2 \|\tilde{x}\| \hat{V}$$

Therefore:

$$\begin{array}{rcl} \mathit{net}_{\hat{v}} & = & \hat{V}\hat{\bar{x}} \\ \mathit{net}_{\hat{w}} & = & \hat{W}\sigma(\hat{V}\hat{\bar{x}}). \end{array}$$

 $ightharpoonup \frac{\partial J}{\partial \hat{M}}$  and  $\frac{\partial J}{\partial \hat{M}}$  can be computed according to

$$\begin{array}{ccc} \frac{\partial J}{\partial \hat{W}} & = & \frac{\partial J}{\partial net_{\hat{w}}}.\frac{\partial net_{\hat{w}}}{\partial \hat{W}} \\ \frac{\partial J}{\partial \hat{V}} & = & \frac{\partial J}{\partial net_{\hat{v}}}.\frac{\partial net_{\hat{v}}}{\partial \hat{V}} \end{array}$$

Farzaneh Abdollahi Neural Networks Lecture 7 16/30

$$\begin{split} \frac{\partial J}{\partial net_{\hat{w}}} &= \frac{\partial J}{\partial \tilde{x}}.\frac{\partial \tilde{x}}{\partial \hat{x}}.\frac{\partial \hat{x}}{\partial net_{\hat{w}}} = -\tilde{x}^T.\frac{\partial \hat{x}}{\partial net_{\hat{w}}} \\ \frac{\partial J}{\partial net_{\hat{v}}} &= \frac{\partial J}{\partial \tilde{x}}.\frac{\partial \tilde{x}}{\partial \hat{x}}.\frac{\partial \hat{x}}{\partial net_{\hat{v}}} = -\tilde{x}^T.\frac{\partial \hat{x}}{\partial net_{\hat{v}}} \end{split}$$

and

$$\begin{array}{rcl} \frac{\partial \operatorname{net}_{\hat{w}}}{\partial \hat{W}} & = & \sigma(\hat{V}\hat{x}) \\ \frac{\partial \operatorname{net}_{\hat{v}}}{\partial \hat{V}} & = & \hat{x} \\ \frac{\partial \dot{\hat{x}}(t)}{\partial \operatorname{net}_{\hat{w}}} & = & A \frac{\partial \hat{x}}{\partial \operatorname{net}_{\hat{w}}} + \frac{\partial \hat{g}}{\partial \operatorname{net}_{\hat{w}}} \\ \frac{\partial \dot{\hat{x}}(t)}{\partial \operatorname{net}_{\hat{v}}} & = & A \frac{\partial \hat{x}}{\partial \operatorname{net}_{\hat{v}}} + \frac{\partial \hat{g}}{\partial \operatorname{net}_{\hat{v}}}. \end{array}$$

▶ Which is dynamic BP. Modify BP algorithm s.t. the static approximations of  $\frac{\partial \hat{x}}{\partial net_{\hat{w}}}$  and  $\frac{\partial \hat{x}}{\partial net_{\hat{v}}}$  ( $\hat{x} = 0$ )

Farzaneh Abdollahi Neural Networks Lecture 7 17/30

$$\frac{\partial \hat{x}}{\partial net_{\hat{w}}} = -A^{-1}$$

$$\frac{\partial \hat{x}}{\partial net_{\hat{v}}} = -A^{-1}\hat{W}(I - \Lambda(\hat{V}\hat{x}))$$

where

$$\Lambda(\hat{V}\hat{x}) = diag\{\sigma_i^2(\hat{V}_i\hat{x})\}, i = 1, 2, ..., m.$$

Finally

$$\dot{\hat{W}} = -\eta_1 (\tilde{x}^T A^{-1})^T (\sigma(\hat{V}\hat{x}))^T 
- \rho_1 ||\tilde{x}|| \hat{W} 
\dot{\hat{V}} = -\eta_2 (\tilde{x}^T A^{-1} \hat{W} (I - \Lambda(\hat{V}\hat{x})))^T \hat{x}^T 
- \rho_2 ||\tilde{x}|| \hat{V}$$

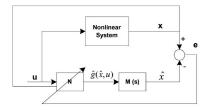

- $\tilde{W} = W \hat{W}$  and  $\tilde{V} = V \hat{V}$ .
- ▶ It can be shown that  $\tilde{x}$ ,  $\tilde{W}$ , and  $\tilde{V} \in L_{\infty}$
- ▶ The estimation error and the weights error are all ultimately bounded [2].

Farzaneh Abdollahi Neural Networks Lecture 7 18/30

#### ► Series-Parallel Identifier

- ► The function g can be approximated by  $\hat{g}(x, u) = \hat{W}\sigma(\hat{V}\bar{x})$
- Only  $\hat{\bar{x}}$  is changed to  $\bar{x}$ .
- ► The error dynamics  $\dot{\tilde{x}}(t) = A\tilde{x} + \tilde{W}\sigma(\hat{V}\bar{x}) + w(t) \text{ where } w(t) = W[\sigma(V\bar{x}) \sigma(\hat{V}\bar{x})] + \epsilon(x)$
- only definition of w(t) is changed.
- ► Applying this change, the rest remains the same

Farzaneh Abdollahi Neural Networks Lecture 7 19/30

- ► The Space Station Remote Manipulator System (SSRMS) is a 7 DoF robot which has 7 revolute joints and two long flexible links (booms).
- ▶ The SSRMS have no uniform mass and stiffness distributions. Most of its masses are concentrated at the joints, and the joint structural flexibilities contribute a major portion of the overall arm flexibility.
- Dynamics of a flexible-link manipulator

$$M(q)\ddot{q} + h(q,\dot{q}) + Kq + F\dot{q} = u$$

- $u = [\tau^T \ 0_{1 \times m}]^T, \ q = [\theta^T \ \delta^T]^T$
- $\theta$  is the  $n \times 1$  vector of joint variables
- $\delta$  is the  $m \times 1$  vector of deflection variables
- ▶  $h = [h_1(q, \dot{q}) \ h_2(q, \dot{q})]^T$ : including gravity, Coriolis, and centrifugal forces;
- M is the mass matrix,
- $K = \begin{bmatrix} 0_{n \times n} & 0_{n \times m} \\ 0_{m \times n} & K_{m \times m} \end{bmatrix}$  is the stiffness matrix,
- $ightharpoonup F = diag\{F_1, F_2\}$ : the viscous friction at the hub and in the structure,

 $\tau$ : input torque.

Neural Networks Lecture 7

http://english.sohu.com/20050729/n226492517.shtml

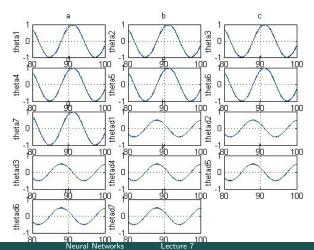

Neural Networks Lecture 7 Farzaneh Abdollahi 21/30

- ▶ A joint PD control is applied to stabilize the closed-loop system ↔ boundedness of the signal x(t) is assured.
- For a two link flexible manipulator

- ▶ The input:  $u = [\tau_1, ..., \tau_7]$
- ▶ A is defined as  $A = -2I \in \mathbb{R}^{22 \times 22}$
- Reference trajectory: sin(t)
- ▶ The identifier:
  - Series-parallel
  - A three-layer NN network: 29 neurons in the input layer, 20 neurons in the hidden layer, and 22 neurons in the output layer.
  - ▶ The 22 outputs correspond to
    - 7 joint positions
    - 7 joint velocities
    - 4 in-plane deflection variables
    - 4 out-of plane deflection variables

The learning rates and damping factors:  $\eta_1=\bar{\eta}_2=0.1,\ \bar{\rho}_1=\bar{\rho}_2=0.00$ 

► Simulation results for the SSRMS: (a-g) The joint positions, and (h-n) the joint velocities.

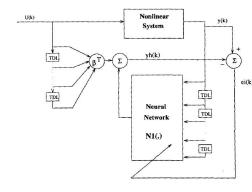

#### Example 2: TDL

Consider the following nonlinear system

$$y(k) = f(y(k-1), ..., y(k-n))$$
  
+  $b_0 u(k) + ... + b_m u(k-m)$ 

- u: input, y:output, f(.): an unknown function.
- Open loop system is stable.
- Objective: Identifying f
- Series-parallel identifier is applied.
- $\beta = [b_0, b_1, ..., b_m]$
- ► Cost function:  $J = \frac{1}{2}e_i^2$  where  $e_i = v - v_h$

Farzaneh Abdollahi Neural Networks Lecture 7 24/30

- ▶ In sigmoidal function. $\sigma$ , the weights of first layer is fixed V = I:  $\sigma_i(\bar{x}) = \frac{2}{1 + \exp^{-2\bar{x}}} - 1$
- ▶ Updating law:  $\triangle w = -\eta(\frac{\partial J}{\partial w})$
- $\blacktriangleright :: \frac{\partial J}{\partial w} = \frac{\partial J}{\partial e_i} \frac{\partial e_i}{\partial w} = -e_i \frac{\partial N(.)}{\partial w}$
- $ightharpoonup \frac{\partial N(.)}{\partial w}$  is obtained by BP method.
- ▶ Numerical Example: Consider a second order system

$$y_p(k+1) = f[y_p(k), y_p(k-1)] + u(k)$$

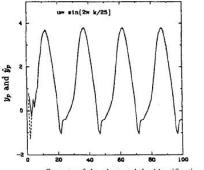

where 
$$f[y_p(k), y_p(k-1)] = \frac{y_p(k)y_p(k-1)[y_p(k)+2.5]}{1+y_p^2(k)+y_p^2(k-1)}$$
.

- After checking the stability system
- Apply series-parallel identifier
- $\triangleright$  u is random signal informally is distributed in [-2, 2]
- n = 0.25

# Numerical Example Cont'd

▶ The outputs of the plant and the model after the identification procedure

Outputs of the plant and the identification model.

Farzaneh Abdollahi Neural Networks Lecture 7 26/30

- A gray box identification, the system model is known but it includes some unknown, uncertain and/or time-varying parameters) is proposed using Hopfield networks
- Consider

$$\dot{x} = A(x, u(t))(\theta_n + \theta(t))$$
  
 $y = x$ 

- v is the output.
- $\triangleright$   $\theta$  is the unknowntime-dependant deviation from the nominal values
- A is a matrix that depends on the input u and the state x
- y and A are assumed to be physically measurable.
- ▶ Objective: estimating  $\theta$  (i.e. min the estimation error:  $\tilde{\theta} = \theta \hat{\theta}$ ).

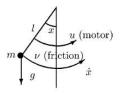

At each time interval assume time is frozen so that

$$A_c = A(x(t), u(t)), \ y_c = y(t)$$

- ► Recall Gradient-Type Hopefield  $C\frac{du}{dt} = Wv(t) + I$
- ► the weight matrix and the bias vector are defined:

$$W = -A_c^T A_c, \ I = A_c^T A_c \theta_n - A_c^T y_c$$

- ► The convergence of the identifier is proven using Lyapunov method
- ► It is examined for an idealized single link manipulator  $\ddot{x} = -\frac{g}{l} \sin x \frac{v}{ml^2} \dot{x} + \frac{1}{ml^2} u$
- ▶ assume  $A = (sinx, \dot{x}, u)$  and  $\theta_n + \theta = (-\frac{g}{l}, -\frac{v}{ml^2}, \frac{1}{ml^2})$

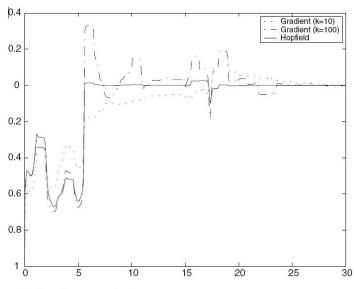

Single link manipulator.
